

Solar Savings

Student Objective

The student:

- given the size of their school's photovoltaic array, the amount of available sunlight and a fixed rate for electricity, will calculate the monetary savings to the school daily, monthly and yearly
- given their family's electricity usage, will calculate the array size needed for their home to be a 'zero energy' home

Key Words:

conservation
energy efficiency
kilowatt hours
zero energy home

Time:

2 class periods

Materials:

- insolation (irradiance) charts for your latitude/climate pattern (or Insolation charts from the *Good Day Sunshine!* activity)
- electricity bill or online access to family's electricity usage

Background

A “**net zero energy**” building or home is one that produces as much electricity as it uses over the course of a year. Most zero energy homes are also connected to the utility grid. When this is the case, it is not important that the energy produced equals the energy used in a minute-to-minute situation, or even on a daily basis. Electricity is purchased from the utility when the system isn't producing enough for the home's demand (nighttime for example), and then sold back to the utility when the system is producing more than the building needs (when the sunlight is intense, when no one is home, or on very sunny days). This averages out the production and the usage to equal zero or near zero. The graph on the next page from the first “zero energy” home research in the United States, done by the Florida Solar Energy Center in Lakeland Florida, demonstrates this fact.

In the graph you can see that when the Sun isn't shining in the morning and evening, the homeowners are buying their power from the power company (green line). But during the day when the Sun is bright and the photovoltaics are producing power (red line), the homeowners are actually “selling” power back to the utility (green line dips below zero).

The interesting thing for Florida homeowners is the near match that the output from a photovoltaic array (red line) makes with the energy consumption of the house (blue line). When our houses are needing the most electricity for air conditioning, the systems are also producing the most power. If you're interested in more information about this study, the link to the zero energy home research (and this particular one in Lakeland Florida), is located in the Internet Sites section.

Because of the size and cost of photovoltaic systems, it is advantageous to improve the **energy efficiency** of a building before buying and installing enough photovoltaics to make the building "zero energy". Research has shown that doing the energy **retrofits** listed below will reduce energy usage in a home by 56%. Listed in order from the easiest and most cost effective to the larger retrofits are:

- Install a programmable thermostat.
- Fix leaky ductwork.
- Replace incandescent lightbulbs with compact florescent or LED lighting.
- Insulate hot water storage tank.
- Upgrade ceiling insulation.
- Replace old refrigerator with an Energy Star model (and get rid of the old refrigerator in the garage!).
- Install a solar thermal hot water system.
- Install a energy efficient air conditioner.

In Florida, 51% of our electricity is used by our homes. By reducing the amount of conventionally produced electricity needed to power our homes, we can dramatically decrease the amount of pollution, and other harmful environmental effects.

Procedure (prior to class)

1. Send a note home advising the parents that the students will be learning how to calculate their family's electrical use with the goal of energy conservation and saving money. Request that a copy of the family electric bill (or a printout of energy use from the utility website) be brought to school by the student. Any sensitive information, and the actual dollar total, can be obscured. All that will be needed for the activity is the total kWh of

- electricity consumed during the month.
2. For students that are unable to obtain their family's bill, have copies of an anonymous bill available for them to use.

Procedure (during class)

1. If necessary, divide the students into groups according to how many computers are available to them.
2. Lead a review discussion on their findings during the *Good Day Sunshine!* activity. Make sure the students understand that now they are talking about the electricity production over time (instead of the instantaneous measurement that they took in their first activities) . They should understand the difference in units between an instantaneous power reading (watts, kilowatts) and the measure of electricity over time (watt hours, kilowatt hours)
3. Tell that students that now they have all the tools they need to be able to predict how much electricity their school's system will produce next month, and also how much money the system will save the school in electricity that will not have to be bought from the power company.
4. Students should complete Problems 1 – 3 in their Science Journals using insolation charts from the same latitude and climate pattern as your school's location. If local charts aren't available, the insolation chart from the *Good Day Sunshine!* activity for Orlando may be substituted.
5. Assist the students as needed.
6. Note: There are two different ways to attack the calculation in question 3. Students can either figure each month's savings separately and then add them together, or they could figure each months total Peak Sun Hours, add them together to get a yearly total Peak Sun Hours and then multiply this times the system size and the cost of electricity.
7. Have the students share how they calculated the total, encouraging them to see that because multiplication is distributive, there are at least two different ways the problem could be approached.

Key Words & Definitions

- **conservation** – the preservation and careful management of natural resources
- **energy efficiency** – the process of doing more with less
- **kilowatt hours (kWh)** – the standard unit used to describe electricity usage over time
- **zero energy home** – a home that produces as much energy as it uses when averaged over a year

Related Research

1. Calculate what size array would be needed to make your home a zero energy home at your current electricity usage. Research energy efficiency measures that you could use to reduce your electricity consumption, and then calculate what size array would be needed to make your 'improved' home a zero energy home. If the current price of photovoltaics is \$3 a watt, how much would be saved by doing the energy efficient retrofits first? Would it be worth it?

2. Research other zero energy homes in Florida and other areas.

Sixth Grade Benchmarks

Science–Big Idea 1: The Practice of Science

- **SC6.N.1.1** - Define a problem from the sixth grade curriculum, use appropriate reference materials to support scientific understanding, plan and carry out scientific investigation of various types, such as systematic observations or experiments, identify variables, collect and organize data, interpret data in charts, tables, and graphics, analyze information, make predictions, and defend conclusions.

Seventh Grade Benchmarks

Science–Big Idea 1: The Practice of Science

- **SC7.N.1.1** - Define a problem from the seventh grade curriculum, use appropriate reference materials to support scientific understanding, plan and carry out scientific investigation of various types, such as systematic observations or experiments, identify variables, collect and organize data, interpret data in charts, tables, and graphics, analyze information, make predictions, and defend conclusions.

Science–Big Idea 11: Energy Transfer & Transformations

- **SC.7.P.11.2** - Investigate and describe the transformation of energy from one form to another.

Mathematics–The Number System

- **MAFS.7.NS.1.3** - Solve real-world and mathematical problems involving the four operations with rational numbers.

Eighth Grade Benchmarks

Science–Big Idea 1: The Practice of Science

- **SC8.N.1.1** - Define a problem from the eighth grade curriculum, use appropriate reference materials to support scientific understanding, plan and carry out scientific investigation of various types, such as systematic observations or experiments, identify variables, collect and organize data, interpret data in charts, tables, and graphics, analyze information, make predictions, and defend conclusions.

\$olar \$avings

1. How much electricity will your school’s photovoltaic system produce this month (assuming that this month is an “average” month)? To figure this out:
 - Multiply the size of your school’s system in kilowatts by the number of Peak Sun Hours per day for this month. That will give you the kilowatt hours per day your system produces.

For the month of _____, the average kilowatt hours per day: _____ kWh

- Multiply the daily total by the number of days in the month to get the total kilowatt hours of electricity that it is expected will be produced this month.

For the month of _____ it is expected that our school’s system will produce _____ kWh of electricity.

2. How much money is the school saving this month by producing some of the electricity being used by photovoltaics rather than buying it from the electric company? (Use 12¢ per kilowatt hour for electricity cost)

3. How much money will the school save each year? (Remember: Peak Sun Hours and the total number of days each month will vary). Show your work below and on the next page.

4. If you could move the photovoltaic system at your school to your home and hook it up there, would it produce all the electricity that your household currently uses? (Use your family's electricity bill, or one supplied by your teacher to compare the electrical output you calculated for your system with your family's usage).

The system provides _____ more electricity than my household uses.

_____ less electricity than my household uses.

Calculate how many panels (or what %) could be removed, or would need to be added, to make the system a good size for your family's electrical needs. (Either show your work or describe below how you calculated your answer.)
